

REMARKS

Claims 1-3 and 5-15 are pending. Claims 1, 7 and 15 are the independent claims.

35 U.S.C. § 112, Second Paragraph

Claims 1 and 6 have been amended in an effort to overcome the § 112, second paragraph rejection. It is respectfully submitted that all claims are now fully definite.

35 U.S.C. §§ 102 and 103

The device disclosed in the Chen document includes a bolt 38 having non-cylindrical portion 380 that is received in a non-cylindrical channel 372 to prevent rotation of the bolt in the channel when the wing-nut 39 is adjusted on the bolt. Owing to the non-cylindrical portion 380 and channel 372, the bolt 38 can never be rotated in the channel to adjust the position of the wing-nut on the bolt (the ability to freely rotate the wing-nut as desired eliminates the need for any such adjustment – the wing-nut can simply be advanced further).

In contrast, the present invention requires that the screw 80 be restrained against unintended rotation by friction while still being selectively rotatable upon application of torque to the head thereof. This ability to selectively rotate the screw 80 allows the position of the lever 90 on the screw to be adjusted so as to adjust the clamping force achievable upon a single stroke of the lever 90. A user of a device formed in accordance with the present invention can periodically apply torque to the head of the screw to fine-tune the clamping force so that a single stroke of the lever provides sufficient clamping force.

The claims have been amended to clarify this aspect of the present invention. As such, it is respectfully submitted that all claims are now in condition for allowance.

Respectfully submitted,

Steven M. Haas

VERSION WITH MARKINGS TO SHOW CHANGES MADE**IN THE CLAIMS**

Claims 1, 6, 7 and 15 have been amended as follows:

1. (Twice Amended) A lock for temporarily fixedly securing first and second associated pole sections in a telescoped arrangement, said lock comprising:

 a base defining an axially extending through-bore adapted for close sliding receipt of an end portion of a first associated pole section;

 a neck projecting from said base;

 a collar connected to said neck and radially constrictable relative to said base, said collar defining an opening aligned with said axially extending through-bore of said base, said collar adapted for close sliding receipt of a second associated pole section partially telescoped into said first associated pole section, wherein said collar is defined by first and second collar portions connected to said neck and terminating in respective first and second ears arranged in spaced-apart relation to each other, said ears defining respective first and second bores;

 a fastener extending through said first and second bores between said first and second ears, said fastener including a head abutting said first ear, an unthreaded first portion frictionally engaged with a portion of said first ear that defines said first bore to inhibit unintentional rotation of said fastener and a threaded distal end extending through said second bore defined in said second ear and projecting outwardly from said second ear;

 a lever having a head defining a threaded aperture that is threadably engaged with said threaded distal end of said fastener, said lever movable rotatably relative to said threaded distal end of said fastener between an unlocked position [, wherein] in which said collar slidably receives and accommodates [a] the second associated pole section, and a

locked position [, wherein] in which said head of said lever is advanced on said threaded distal end of said fastener toward said head of said fastener and urges said second ear toward said first ear to constrict said collar radially relative to said base into frictional gripping engagement with [a] the second associated pole section received in the collar, wherein said first portion of said fastener defines an unthreaded cylindrical conformation that is located in said first bore defined by said first ear with a tight frictional fit sufficient to restrain said fastener against rotation [upon] in response to movement of said lever between said unlocked and said locked positions, wherein said fastener is selectively rotatable via application of torque to said head sufficient to overcome said tight frictional fit between said unthreaded cylindrical conformation and said first ear.

6. (Twice Amended) The lock as set forth in claim [4]1, wherein said threaded distal end of said fastener defines a double lead left-handed thread.

7. (Twice Amended) A telescoping pole apparatus comprising:
a first pole section defining a first bore;
a second pole section slidably located in said first bore of said first pole section in a telescoping arrangement;
a lock connected to said first pole section and adapted to secure said second pole section axially relative to said first pole section, said lock comprising:
a base defining an axial through-bore, wherein an end portion of said first pole section is located in said axial through-bore;
a collar connected to said base and selectively radially constrictable relative to said base, said collar defining an opening aligned with said axial through-bore, said second pole section projecting from said first bore of said first pole section

and through said opening of said collar, said collar, when radially constricted relative to said base, firmly engaging and retaining said second pole section in an axially and rotatably fixed position relative to said first pole section;

a fastener connected to and frictionally engaged with said collar so as to be restrained against unintended rotation relative to said collar, said fastener comprising a head at a first end and a threaded second end that projects outwardly from said collar; and

a control member that mates threadably with said threaded end of said fastener, said control member selectively manually rotatable relative to said fastener in first and second directions to constrict and expand said collar radially, respectively, said fastener restrained against rotation with said control member by frictional engagement between said fastener and said collar, wherein said fastener is selectively rotatable upon application of torque to said head sufficient to overcome said frictional engagement between fastener and said collar.

15. (Twice Amended) A lock apparatus for fixedly securing first and second telescoping pole sections relative to each other, said apparatus comprising:

a first portion adapted for connection to an end portion of a first associated pole section;

a second portion connected to said first portion and defining a collar that is selectively radially constrictable relative to said first portion and adapted for receipt of a second associated pole section partially telescoped into said first associated pole section,

said collar, when radially constricted, firmly engaging and fixedly retaining a second associated pole section received thereby, said collar comprising first and second ears separated from each other by a space;

a screw extending through said first and second ears of said collar and including a headed end and an opposite threaded end, said screw comprising an unthreaded cylindrical portion that is tightly frictionally engaged with only one of said first and second ears, said screw selectively manually rotatable relative to said first and second ears upon application of sufficient torque to said headed end to overcome said frictional engagement between said cylindrical portion of said screw and said one of said first and second ears; and

a lever operably coupled to said threaded end of said screw and adapted for rotation in a first direction on said screw causing said lever to be advanced on said screw towards said headed end so that said collar is radially constricted, and adapted for rotation in a second direction opposite said first direction so that said lever moves away from said headed end of said screw and said collar resiliently radially expands, wherein said tight frictional engagement between said unthreaded portion of said screw and said one of said first and second ears restrains said screw against unintended rotation with said lever when said lever is moved in said first and second directions.
